

**Problem 1.** For an  $n \times n$  matrix  $A$ , where

$$A_{1,1} = 2, \quad A_{1,2} = -1, \quad A_{n,n} = 2, \quad A_{n-1,n} = -1$$

and

$$A_{i,i} = 2, \quad A_{i,i+1} = -1, \quad A_{i,i-1} = -1, \quad \forall i \neq 1, n$$

and  $A_{i,j} = 0$  otherwise. Compute its LU factorization with MATLAB/Python. Can the LU factorization be obtained faster than  $O(n^3)$  complexity? If so, what would the algorithm be?

*Solution:* The matrix  $A$  is the following form:

$$A = \begin{bmatrix} 2 & -1 & 0 & \cdots & 0 & 0 & 0 \\ -1 & 2 & -1 & \ddots & \vdots & \vdots & \vdots \\ 0 & -1 & 2 & \ddots & -1 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & 2 & -1 & 0 \\ 0 & \cdots & -1 & 2 & -1 & \ddots & \vdots \\ 0 & \cdots & 0 & -1 & 2 & -1 & \\ 0 & \cdots & 0 & 0 & -1 & 2 & \end{bmatrix}$$

The code is as follows:

```

1  A = generate_tridiagonal_matrix(5);
2  [L_A, U_A] = LU_decomp(A);
3
4
5  function A = generate_tridiagonal_matrix(n)
6      % Generates an n x n symmetric tridiagonal matrix with:
7      % 2 on the diagonal and -1 on the sub- and super-diagonals
8
9      e = ones(n,1);
10     A = 2*diag(e) - diag(e(1:end-1),1) - diag(e(1:end-1),-1);
11 end
12
13 function [L, U] = LU_decomp(A)
14     n_tuple = size(A);
15     assert(n_tuple(1) == n_tuple(2));
16     n = n_tuple(1);
17     U = A;
18     L = eye(n_tuple(1), n_tuple(2));
19     for j = 1:n
20         for i = j+1:n
21             if U(j,j) == 0
22                 error("entry in U is 0");
23             end
24             L(i,j) = U(i,j) / U(j,j);
25             U(i, j:n) = U(i,j:n) - L(i,j) * U(j,j:n);

```

```

26         end
27     end
28 end

```

Note that given the matrix is a tridiagonal matrix, we know that we can remove the  $\square$

**Problem 2.** Implement a gradient descent method (with fixed step size) to solve

$$\min_{x \in \mathbb{R}^n} \frac{1}{2} (x - x_*)^T A (x - x_*)$$

where  $x_* = [1, 2, \dots, n]^T$ . What is the complexity per step of gradient descent? (Show the complexity as  $n$  grows using a plot). Furthermore, by repeating the experiment for different  $n$ , extract the rate of convergence and show its dependency on  $n$  using big-O notation.

**Problem 3.** Repeat Problem 2 by implementing a conjugate gradient method.

**Problem 4.** Suppose in a gradient descent scheme, an error  $\epsilon_k$  occurs:

$$x^{(k+1)} = x^{(k)} - s_k \nabla f(x^{(k)}) + \epsilon_k$$

where  $\|\epsilon_k\| \leq \epsilon$ , and  $f = \frac{1}{2} (x - x_*)^T A (x - x_*)$  with  $A$  positive definite. Show the scheme can converge with a suitable choice of  $s_k$ .
